# Automatic Parallelization of Example Code

Let's try automatic parallelization.

Compiling with `solarisstudio` and automatic parallelization yields the following:

---

```
% solarisstudio-cc -O3 -xautopar -xloopinfo omp_vector.c  
"omp_vector.c", line 5: PARALLELIZED, and serial version generated  
"omp_vector.c", line 15: not parallelized, call may be unsafe
```

---

How will this code compare to our manual efforts?  
(If you weren't in class, you'll have to try it yourself.)

**Note:** `solarisstudio` generates two versions of the code, and decides, at runtime, if the parallel code would be faster.

# Example Code to Parallelize

---

```
#include <stdlib.h>

void setup(double *vector, int length) {
    int i;
    for (i = 0; i < length; i++)
    {
        vector[i] += 1.0;
    }
}

int main()
{
    double *vector;
    vector = (double*) malloc(sizeof(double)*1024*1024);
    for (int i = 0; i < 1000; i++)
    {
        setup (vector, 1024*1024);
    }
}
```

---

# Automatic Parallelization of Example Code

Let's try automatic parallelization.

Compiling with `solarisstudio` and automatic parallelization yields the following:

---

```
% solarisstudio-cc -O3 -xautopar -xloopinfo omp_vector.c  
"omp_vector.c", line 5: PARALLELIZED, and serial version generated  
"omp_vector.c", line 15: not parallelized, call may be unsafe
```

---

How will this code compare to our manual efforts?  
(If you weren't in class, you'll have to try it yourself.)

**Note:** `solarisstudio` generates two versions of the code, and decides, at runtime, if the parallel code would be faster.

# Autoparallelization implementation: OpenMP

Under the hood, most parallelization frameworks use OpenMP, which we'll see next lecture.

For now: you can control the number of threads with the `OMP_NUM_THREADS` environment variable.

gcc (since 4.3) can also auto-parallelize loops.  
However, there are a few problems:

- 1 It will not tell you which loops it parallelizes (nicely).
- 2 It only operates with a fixed number of threads.
- 3 The profitability metrics are quite simple.
- 4 Only operates in simple cases.

Use the flags `-floop-parallelize-all` `-ftree-parallelize-loops=N`  
where N is the # of threads.

**Note:** gcc also uses OpenMP but ignores `OMP_NUM_THREADS`.

# Understanding Automatic Parallelization in gcc

Flag `-fdump-tree-parloops-details` shows what the automatic parallelizations were, but it's quite unreadable.

Instead, you can look at the assembly code to see the parallelizations (obviously, impractical for a large project).

---

```
% gcc -std=c99 -O3 -ftree-parallelize-loops=4  
  omp_vector_gcc.c -S -o omp_vector_gcc_auto.s
```

---

The resulting `.s` file contains the following code:

---

```
call    GOMP_parallel_start  
leaq    80(%rsp), %rdi  
call    setup._loopfn.0  
call    GOMP_parallel_end
```

---

**Note:** gcc also parallelizes `main._loopfn.2` and `main._loopfn.3`, although it looks like it serves little purpose.

# Loops That gcc's Automatic Parallelization Can Handle

## Single loop:

---

```
for (i = 0; i < 1000; i++)  
    x[i] = i + 3;
```

---

## Nested loops with simple dependency:

---

```
for (i = 0; i < 100; i++)  
    for (j = 0; j < 100; j++)  
        x[i][j] = x[i][j] + y[i-1][j];
```

---

## Single loop with not-very-simple dependency:

---

```
for (i = 0; i < 10; i++)  
    x[2*i+1] = x[2*i];
```

---

# Loops That gcc's Automatic Parallelization Can't Handle

Single loop with if statement:

---

```
for (j = 0; j <= 10; j++)  
    if (j > 5) X[i] = i + 3;
```

---

Triangle loop:

---

```
for (i = 0; i < 100; i++)  
    for (j = i; j < 100; j++)  
        X[i][j] = 5;
```

---

# Summary of Conditions for Automatic Parallelization

From Chapter 10 of Oracle's *Fortran Programming Guide*<sup>1</sup> translated to C, a loop must:

- have a recognized loop style, e.g., for loops with bounds that don't vary per-iteration;
- have no dependencies between data accessed in loop bodies for each iteration;
- not conditionally change scalar variables read after the loop terminates, or change any scalar variable across iterations; and
- have enough work in the loop body to make parallelization profitable.

# Manually Parallelizing the Example Code

What can we do to parallelize this code?

**Option 1:**

**Option 2:**

**Option 3:**

# Manually Parallelizing the Example Code

What can we do to parallelize this code?

**Option 1:** horizontal      

- Create 4 threads; each thread does 1000 iterations on its own sub-array.

**Option 2:**

**Option 3:**

# Manually Parallelizing the Example Code

What can we do to parallelize this code?

**Option 1:** horizontal      

- Create 4 threads; each thread does 1000 iterations on its own sub-array.

**Option 2:** bad horizontal      

- 1000 times, create 4 threads which each operate once on the sub-array.

**Option 3:**

# Manually Parallelizing the Example Code

What can we do to parallelize this code?

**Option 1:** horizontal      ≡≡≡≡

- Create 4 threads; each thread does 1000 iterations on its own sub-array.

**Option 2:** bad horizontal      ≡≡≡≡

- 1000 times, create 4 threads which each operate once on the sub-array.

**Option 3:** vertical      |||| |||| |||| ||||

- Create 4 threads; for each element, the owning thread does 1000 iterations on that element.

I'll show a demo of three example PThread parallelizations.

Methodology: compiling with `solarisstudio`,  
flags `-O3 -lpthread`.

Which manual option performs better?

# Comparing Parallelization Results

How does autoparallelization compare to manual parallelization?

## Case Study 2: Multiplying a Matrix by a Vector

Let's see how automatic parallelization does on a more complicated program (could we parallelize this?):

---

```
void matVec (double **mat, double *vec, double *out,
             int *row, int *col)
{
    int i, j;
    for (i = 0; i < *row; i++)
    {
        out[i] = 0;
        for (j = 0; j < *col; j++)
        {
            out[i] += mat[i][j] * vec[j];
        }
    }
}
```

---

$$\text{Reminder: } \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix} \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} = \begin{bmatrix} 14 \\ 32 \end{bmatrix}$$

# Case Study: Automatic Parallelization, Attempt 1

Well, based on our knowledge, we could parallelize the outer loop.

Let's see what solarisstudio will do for us...

---

```
% solarisstudio-cc -xautopar -xloopinfo -O3 -c fploop.c
"fploop.c", line 5: not parallelized, not a recognized for loop
"fploop.c", line 8: not parallelized, not a recognized for loop
```

---

...it refuses to do anything, guesses?

## Case Study: Automatic Parallelization, Attempt 2

- The loop bounds are not constant, since one of the variables may alias `row` or `col`, even though `int`  $\neq$  `double`.

So, let's add `restrict` to `row` and `col` and see what happens...

---

```
% solarisstudio-cc -O3 -xautopar -xloopinfo -c fploop.c  
"fploop.c", line 5: not parallelized, unsafe dependence  
"fploop.c", line 8: not parallelized, unsafe dependence
```

---

Now it recognizes the loop, but still won't parallelize it. Why?

# Case Study: Automatic Parallelization, Attempt 3

- `out` might alias `mat` or `vec`, which would make this unsafe

Let's add another `restrict` to `out`:

---

```
% solarisstudio-cc -O3 -xautopar -xloopinfo -c fploop.c
"fploop.c", line 5: PARALLELIZED, and serial version
    generated
"fploop.c", line 8: not parallelized, unsafe dependence
```

---

Now, we can get the outer loop to parallelize.

- Parallelizing the outer loop is almost always better than inner loops, and usually it's a waste to do both, so we're done.

**Note:** We can parallelize the inner loop as well (it's similar to Assignment 1). We'll see that `solarisstudio` can do it automatically.

# Lingering Questions about Runtimes

What happened here?

≡≡≡≡

horizontal good:

create 4 threads to do 1000 iterations on sub-arrays.

≡≡≡≡

horizontal bad:

1000 times, create 4 threads to iterate on sub-array.

|||| |||| |||| ||||

vertical:

create 4 threads, handle 1 element at a time.

Last year, `perf -r 5` gave following task-clocks (in seconds):

	H good	H bad	V	auto
gcc, no opt	2.794	2.953	2.799	
gcc, -O3	0.588	1.490	0.980	
solaris, no opt	3.175	3.291	2.966	
solaris, -xO4	0.494	1.453	2.739	0.688

## Observations:

- Good runs had 5 to 7 cpu-migrations; bad had 4000.
- # cycles varied from 2B to 9.7B (no opt).
- Branch misses varied from 8k to 208k.

- Reductions combine input data into a smaller (summary) set.
- We'll see a more complete definition when we touch on functional programming.
- Simplest instance: computing the sum of an array.

Consider the following code:

---

```
double sum (double *array, int length)
{
    double total = 0;

    for (int i = 0; i < length; i++)
        total += array[i];
    return total;
}
```

---

Can we parallelize this?

Barriers to parallelization:

- 1 value of `total` depends on previous iterations;
- 2 addition is actually non-associative for floating-point values  
(is this a problem?)

Recall that “associative” means:

$$a + (b + c) = (a + b) + c.$$

in this case, the program probably isn't sensitive to rounding, but you should always consider if an operation is associative.

Barriers to parallelization:

- 1 value of `total` depends on previous iterations;
- 2 addition is actually non-associative for floating-point values  
(is this a problem?)

Recall that “associative” means:

$$a + (b + c) = (a + b) + c.$$

In this case, the program probably isn't sensitive to rounding, but you should always consider if an operation is associative.

# Automatic Parallelization via Reduction

If we compile the program with `solarisstudio` and add the flag `-xreduction`, it will parallelize the code:

---

```
% solarisstudio-cc -xautopar -xloopinfo -xreduction -O3 -c sum.c
"sum.c", line 5: PARALLELIZED, reduction, and serial version
generated
```

---

**Note:** If we try to do the reduction on `fploop.c` with `restricts` added, we'll get the following:

---

```
% solarisstudio-cc -O3 -xautopar -xloopinfo -xreduction -c fploop.c
"fploop.c", line 5: PARALLELIZED, and serial version generated
"fploop.c", line 8: not parallelized, not profitable
```

---

- A general function could have arbitrary side effects.
- Production compilers tend to avoid parallelizing any loops with function calls.

Some built-in functions, like `sin()`, are “pure”, have no side effects, and are safe to parallelize.

**Note:** this is why functional languages are nice for parallel programming: impurity is visible in type signatures.

# Dealing with Function Calls in `solarisstudio`

- For `solarisstudio` you can use the `-xbuiltin` flag to make the compiler use its whitelist of “pure” functions.
- The compiler can then parallelize a loop which uses `sin()` (you shouldn't replace built-in functions with your own if you use this option).

Other options which may work:

- 1 Crank up the optimization level (`-xO4`).
- 2 Explicitly tell the compiler to inline certain functions (`-xinline=`, or use the `inline` keyword).

# Summary of Automatic Parallelization

To help the compiler, we can:

- use `restrict` (make a restricted copy); and,
- make sure that loop bounds are constant (temporary variables).

Some compilers automatically create different versions for the alias-free case and the (parallelized) aliased case.

At runtime, the program runs the aliased case if correct.
