

Lecture 26 —Profiling and Scalability

Jeff Zarnett
jzarnett@uwaterloo.ca

Department of Electrical and Computer Engineering
University of Waterloo

December 3, 2022

Goal: scale number of users,

$1 \rightarrow 100 \rightarrow 10000000.$

Be more fast?

You have other options too...

“In the midnight hour, she cries 'more, more, more'" - Billy Idol

As always, we want to measure (profile).

3 principles to think about
when going from dev to production:

Scalability testing \neq QA testing.

Dev + QA on local computer.

Your concerns: Is it right? Is it fast enough?

Fine, but it's no way to test if it scales.

Test on prod-like machines.

Low-end systems have very different limiting factors.

Your laptop: limited by 16GB of RAM.

Prod server: 128GB of RAM.

So you might spend a great deal of time worrying about RAM usage and it just doesn't matter.

Brennan Keller
@brenankeller

A QA engineer walks into a bar.
Orders a beer. Orders 0 beers.
Orders 999999999999 beers.
Orders a lizard. Orders -1 beers.
Orders a ueicbksjdhd.

First real customer walks in
and asks where the bathroom
is. The bar bursts into flames,
killing everyone.

Quality Assurance

Use a “real” workload.
(As far as possible).

Maybe not actual live customer data,
but try to come close.

Limited test data/scenarios \Rightarrow
inaccurate test results.

Your tests run summary reports occasionally...
your users might run them every hour.

“More is the new more.”

Lighter workloads OK for regression testing.

To see how your system performs under pressure, you actually need to put it under pressure.

Can simulate pressure by limiting RAM or running something very CPU-intensive concurrently, but it's just not the same.

These tests also of great interest to the customers, who would like to know that you can deliver.

Reproducibility and Regression Testing

Science rule 1: results need to be reproducible!

Good programming practice: must run unit tests, and re-run to make sure it all works.

Old (solved) performance issues also bad.

Or a new change that slows the whole program down still more bad.

Elementary, My Dear Watson!

It is a capital mistake to theorize before one has data. Insensibly one begins to twist facts to suit theories, instead of theories to suit facts.

— Sherlock Holmes
(*A Scandal in Bohemia*; Sir Arthur Conan Doyle)

Who's to blame?

- 1 CPU
- 2 Memory
- 3 Disk
- 4 Network

These are, obviously,
categories rather than specific causes.

CPU is probably the easiest of these to diagnose.

htop, Task Manager, etc. will tell you if CPU hosed.
Look at the %CPU columns
and see where all your CPU is going.

Still, that tells you about right now;
what about the long term average?

Checking with my machine “Loki”, that has since ascended to Valhalla:

```
top - 07:28:19 up 151 days, 23:38,  8 users,  load average: 0.87, 0.92, 0.91
```

Those last three numbers are the one, five, and fifteen minute averages of CPU load, respectively.

Lower numbers mean less CPU usage and a less busy machine.

Picture a single core of a CPU as a lane of traffic.

You are a bridge operator and so you need to monitor how many cars are waiting to cross that bridge.

If no cars are waiting, traffic is good and drivers are happy.

If there is a backup of cars, then there will be delays.

- 1** 0.00 means no traffic.
Anything between 0.00 and 0.99 means we're under capacity and there will be no delay.
- 2** 1.00 means we are exactly at capacity.
Everything is okay, but if one more car shows up, there will be a delay.
- 3** Anything above 1.00 means there's a backup (delay).
If we have 2.00 load, then the bridge is full and there's an equal number of cars waiting to get on the bridge.

= load of 1.00

= load of 0.50

= load of 1.70

≥ 1.00 isn't necessarily bad, but you should be concerned if there is consistent load of 1.00 or above.

< 1.00 but getting close to it: you know how much room you have to scale things up.

> 0.70 then it's probably time to investigate.

≥ 1.00 consistently we have a serious problem.

5.00: this is a red alert situation.

Now this is for a single CPU—if you have a load of 3.00 and a quad core CPU, this is okay.

Traffic analogy: four lanes of traffic, of which 3 are being used to capacity.

So we have a fourth lane free and it's as if we're at 75% utilization on a single CPU.

How to tell? Look at disk utilization.

Not enough RAM \Rightarrow swapping, bad perf, no scalability.

(In the worst case.)

You can ask via `top` about how much swap is being used, but that's probably not the interesting value.

```
KiB Mem:  8167736 total,  6754408 used,  1413328 free,   172256 buffers
KiB Swap:  8378364 total,  1313972 used,  7064392 free.  2084336 cached Mem
```

Why? Memory being “full” does not necessarily mean anything bad.

It means the resource is being used to its maximum potential, yes, but there is no benefit to keeping a block of memory open for no reason. (Or stockpiling late days).

Also, memory is unlike CPU; if there's nothing for the CPU to do, it will just idle (low power state).

Memory won't "forget" data if it doesn't happen to be needed right now—data will hang around in memory until there is a reason to move or change it.

So freaking out about memory appearing as full is kind of like getting all in a knot about how "System Idle Process" is hammering the CPU...

You can also ask about page faults, with the command

```
ps -eo min_flt,maj_flt,cmd
```

Major page faults: had to fetch from disk.

Minor page faults: had to copy a page from another process.

The output of this is too big even for the notes.

This is process-lifetime data.

What you really want is to ask Linux for a report on swapping:

```
jz@Loki:~$ vmstat 5
```

procs		-----memory-----				---swap--		-----io-----		-system--			-----cpu-----			
r	b	swpd	free	buff	cache	si	so	bi	bo	in	cs	us	sy	id	wa	st
1	0	1313972	1414600	172232	2084296	0	0	3	39	1	1	27	1	72	0	0
0	0	1313972	1414476	172232	2084296	0	0	0	21	359	735	19	0	80	0	0
0	0	1313972	1414656	172236	2084228	0	0	0	102	388	758	22	0	78	0	0
4	0	1313972	1414592	172240	2084292	0	0	0	16	501	847	33	0	67	0	0
0	0	1313972	1412028	172240	2084296	0	0	0	0	459	814	29	0	71	0	0

Swapping Report with Actual Swapping

procs			swpd	free	memory			swap			io		system		cpu
r	b	w			buff	cache	si	so	bi	bo	in	cs	us	sy	
.	.	.													
1	0	0	13344	1444	1308	19692	0	168	129	42	1505	713	20	11	
1	0	0	13856	1640	1308	18524	64	516	379	129	4341	646	24	34	
3	0	0	13856	1084	1308	18316	56	64	14	0	320	1022	84	9	

Looking at disk might seem slightly redundant if memory is not the limiting factor.

After all, if the data were in memory it would be unnecessary to go to disk in the first place.

Still, sometimes we can take a look at the disk and see if that is our bottleneck.

```
jz@Loki:~$ iostat -dx /dev/sda 5  
Linux 3.13.0-24-generic (Loki) 16-02-13 _x86_64_ (4 CPU)
```

Device:	rrqm/s	wrqm/s	r/s	w/s	rkB/s	wkB/s	avgrq-sz	avgqu-sz	await	r_await	w_await	svctm	%util
sda	0.24	2.78	0.45	2.40	11.60	154.98	116.91	0.17	61.07	11.57	70.27	4.70	1.34

Last column %util tells us what we want to know.

We can ask about the network with `nload`.

You get a nice little graph if there is anything to see.

But you'll get the summary, at least:

Curr: 3.32 kBit/s

Avg: 2.95 kBit/s

Min: 1.02 kBit/s

Max: 12.60 kBit/s

Ttl: 39.76 GByte
